

# SIM Swap & Transaction Fraud Risk Analytics — Starter Kit

This folder is the day-1 base for the project. Read in this order:

1. **PRD.md** — what you're building and why.
2. **ARCHITECTURE.md** — how it fits together, with diagrams and the exact repo layout.
3. **TECH\_STACK.md** — locked stack choices + every API key you'll need (most modules need none at all).
4. **TEAM\_ROLES.md** — who owns which folder, so no two people edit the same file.
5. **memory.md** — living decision log; update it whenever the team changes something.

## Quickstart

```
git init simswap-fraud-analytics && cd simswap-  
fraud-analytics  
# copy PRD.md, ARCHITECTURE.md, TECH_STACK.md,  
TEAM_ROLES.md, memory.md into the repo root  
mkdir -p backend/api backend/risk_engine  
backend/db frontend simulators notifications  
tests  
cp TECH_STACK.md .env.example.reference # pull  
the .env.example block out into a real file
```

```
git add . && git commit -m "scaffold: docs +  
folder structure"
```

Then each member creates their branch and starts inside their owned folder from

`TEAM_ROLES.md` — Member A's Flask skeleton and Member B's stubbed risk-engine functions should land first (day 1–2), since A and C both build against them.

## One-line project description

A prototype that scores logins, SIM-change events, and transactions with a hybrid rules + logistic-regression engine, returns ALLOW / STEP\_UP / BLOCK with human-readable reasons, and shows it all live on an analyst dashboard — using synthetic traffic, no real bank or telecom data.
